KIRC/P GA2x vs HiSeq, subsample 5, 35 miRNAs

Differential abundance analysis, edgeR v1.5.1
 A larger set of miRNAs should estimate background variance more effectively.

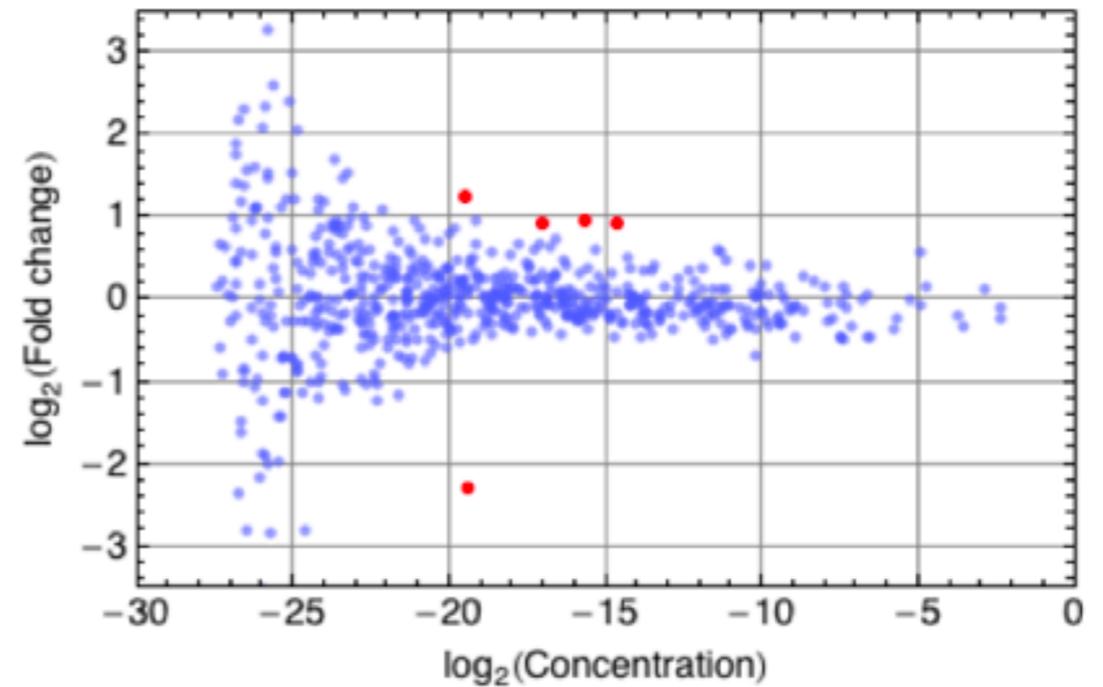

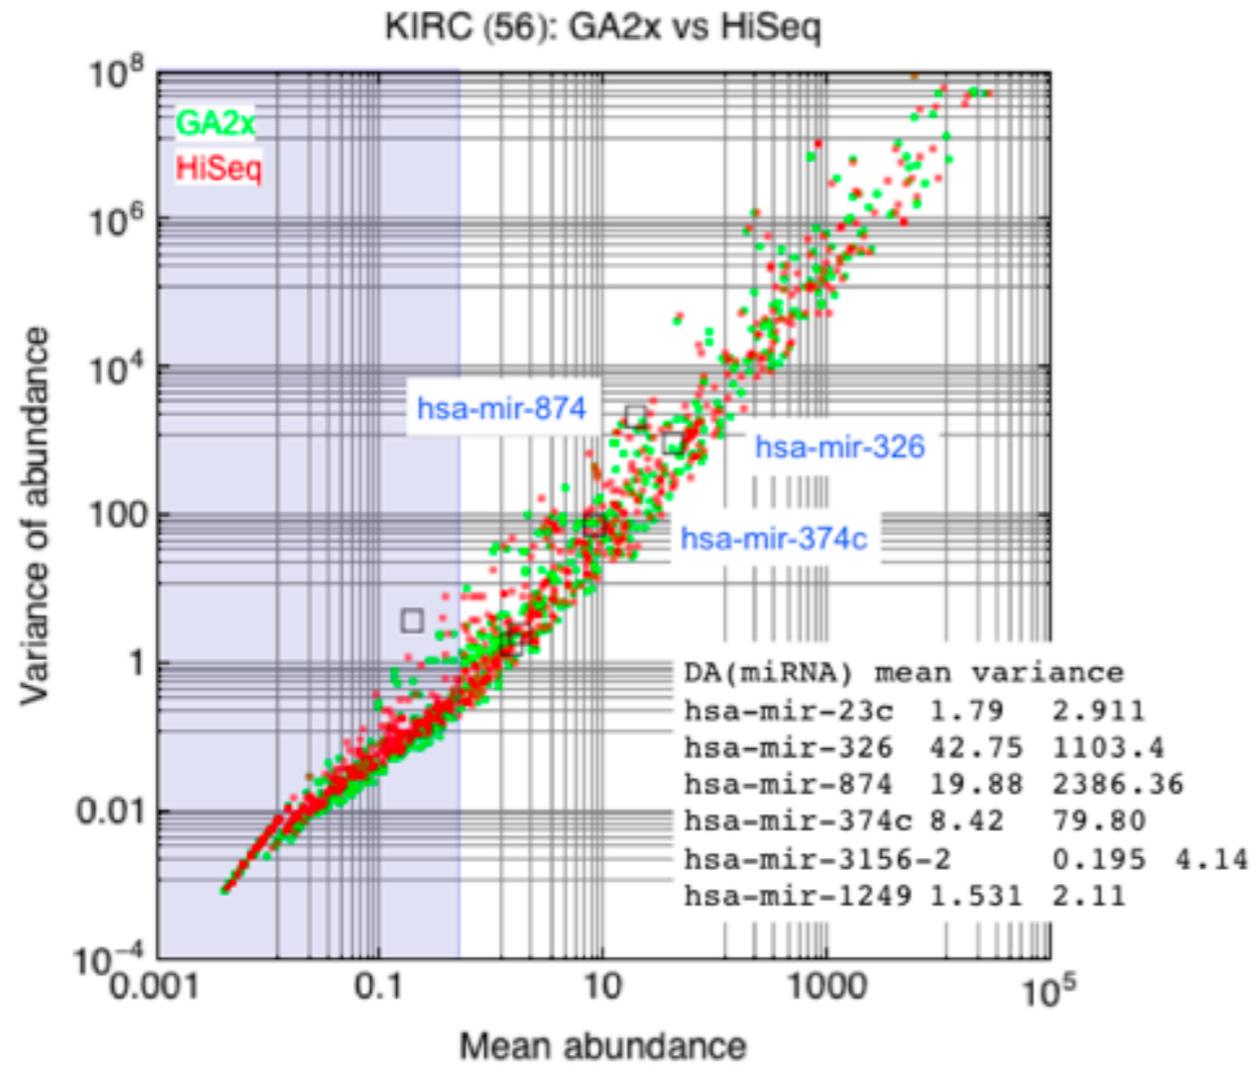

Consensus clustering, Spearman, k-means, 200 iterations
 The two platforms are mixed, i.e. do not clearly separate.

Differential abundance between HiSeq and GA2x

We identified differentially abundant miRNAs between HiSeq and GA2x (1/0) using edgeR v2.2.3 and an expression matrix of 767 miRNAs that had nonzero sums across 2x56 samples. Nine miRNAs had BH-corrected p-val < 0.05 (red in 'a', black squares in 'b', table). As expected, the FC plot ('smearPlot') identified no low-abundance miRNAs as differentially abundant. **hsa-mir-23c** was flagged as having a negative PC1 loading (slide 9), when all other 8 loadings had positive values.

Hi Gordon.

Using all of the tests on the subsampled data we found just one result that was significant. Anecdotally, most tests showed a difference between the two platforms, but only this one was able to differentiate them statistically. In this figure, the GA is green and the High seq is red. The median of the mean normalized expression for this set of microRNAs is ~5000, so we're not talking about noise here.

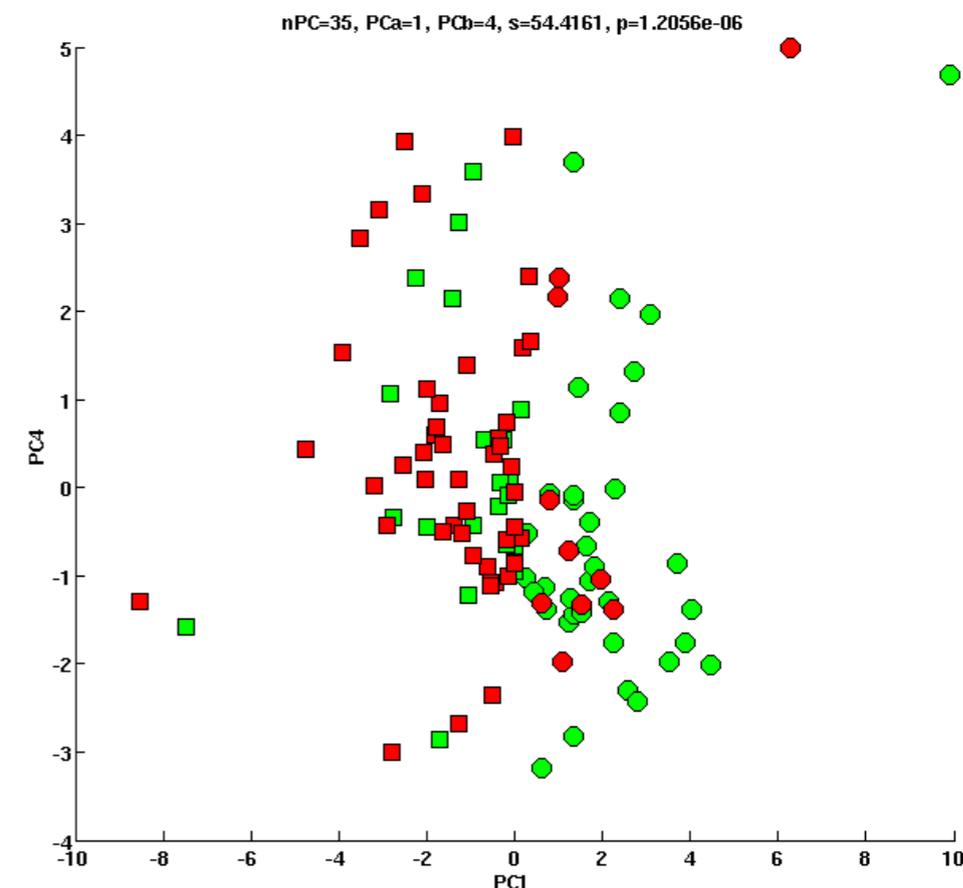

Richard
